(54) DISK ARRAY CONTROLLER AND DISK ARRAY DEVICE

(57) A disk array controller or a disk array system includes a disk array control unit having an MPU 8 and a user data transfer control unit having host interfaces 3 and 4 with a host computer 17, a memory 5 for temporarily storing data, a redundant data generator 7 for generating redundant data, multi-channel disk device interfaces 16a~16e and 12a~12e and a data transfer control circuit (DMAC) 6 for controlling the data transfer between the host interface, the memory, the redundant data generator and the disk device interface. Internal buses are of at least three-bus structure including a control bus (for MPU) 15, a host data bus 13 and a drive data bus 14.

FIG. 1

EP 0 795 812 A1

Description**TECHNICAL FIELD**

The present invention relates to disk array system and disk array controller having an architecture such as RAID5.

BACKGROUND ART

In a prior art disk array controller architecture, one internal bus is used or two buses, that is, a control bus by a built-in MPU and a user data transfer bus between a host interface and a disk device interface are used.

Further, as disclosed in JP-A-6-180623, a dedicated circuit such as a FIFO (First-in First-out) for speed control is needed between the host interface and the disk device.

In the prior art, when the host interface and the disk device interface is of SCSI type, transfer rate and bus width of the internal bus of the disk array controller are limited by a SCSI control LSI used therein.

On the other hand, in order to increase the transfer rate and the bus width of the internal bus of the disk array controller independently from the SCSI controller LSI for increasing the speed of the disk array system, a dedicated circuit such as a FIFO is needed between the SCSI interface and the internal bus, and in a disk array controller having a plurality of channels of host interface and disk device interface, this is a factor of high cost of the disk array controller and the disk array system.

DISCLOSURE OF INVENTION

It is an object of the present invention to provide disk array controller and disk array system which solve the above problems and increases the data transfer rate with a low cost.

It is another object of the present invention to provide a disk array controller and disk array system which reduce a traffic to a memory (disk cache) to improve an effective transfer rate.

It is other object of the present invention to provide disk array controller and disk array system which allow the data scattering/gathering and the parity data generation.

In order to achieve the above objects, the present invention provides a disk array controller or a disk array system which is controller characterized by the provision of a disk array control unit having one or more MPUs; and the provision of a user data transfer unit having a host interface with a host computer, a memory (disk cache) for temporarily storing data, redundant data generation means (REDUNDANT DATA GENERATOR) for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between the host interface, the memory, the redundant data generation means and the disk device

interface; and that a control bus (MPU bus) for controlling the disk device interface, the redundant data generation means and the data transfer control means of the user data transfer control unit by the disk array control unit, a host data bus for conducting the data transfer between the host interface and the memory by the data transfer control means in the user data transfer control unit and a drive data bus for conducting the data transfer between the disk device interface and the memory by the data transfer control means in the user data transfer control unit are provided.

The present invention is further characterized by that, in the disk array controller or the disk array system, the host interface and the disk device interface comprise SCSI (Small Computer System Interface) interfaces such as SCSI-2.

The present invention is further characterized by that in the disk array controller or the disk array system, the data transfer control means allows the designation of a plurality of data transfer paths between areas of the memory and the disk device interface.

The present invention is further characterized by that, in the disk array controller or the disk array system, the data transfer means comprises a plurality of counters for designating addresses of the memory and a plurality of registers for designating channels of the disk device interface corresponding to the respective counters.

The present invention is further characterized by that, in the disk array controller or the disk array system, the data transfer means transfers data between the areas of the memory and the redundant data generation means by using a plurality of transfer paths.

The present invention is further characterized by that, in the disk array controller or the disk array system, that the data transfer control means comprises a DMAC (Direct Memory Access Controller, a portion of a small computer which controls, in place of a CPU or an I/O processor, the data transfer between memory↔memory or between memory↔I/O. It generates a source address and a destination address necessary for the data transfer and drives a read cycle of the source and a write cycle of the destination).

The present invention is further characterized by that, in the disk array controller or the disk array system, the data transfer control means comprises a plurality of counters for designating addresses of the memory and a plurality of registers for designating channels of the disk device interface corresponding to the counters to allow the designation of a plurality of data transfer paths between the areas of the memory and the disk device interface and the input of the data of the corresponding data transfer paths to the redundant data generation means.

The present invention is further characterized by that, in the disk array controller or the disk array system, the disk device interface is provided with drive interface controller one for each channel.

The present invention is further provides a disk

array controller or a disk array system characterized by the provision of a disk array control unit having one or more MPUs; and the provision of a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between the host interface, the memory, the redundant data generation means and the disk device interface; and that a control bus for controlling the multi-channel disk device interface, the redundant data generation means and the data transfer control means of the user data transfer control unit by the disk array control unit, a host data bus for conducting the data transfer between the host interface and the memory by the data transfer control means in the user data transfer control unit and a drive data bus for conducting the data transfer between the disk device interface and the memory by the data transfer control means in the user data transfer control unit are provided, and the redundant data generation means is directly coupled to the data transfer control means and arranged between the memory and the drive data bus to reduce the traffic to the memory during the generation of the redundant data.

The present invention further provides a disk array controller or a disk array system characterized by the provision of a disk array control unit having one or more MPUs; and the provision of a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generator for generating redundant data, a multi-channel disk device interface and data transfer control unit having one or more channels for controlling the data transfer between the host interface, the memory, the redundant data generator and the disk device interface; and that a control bus for controlling the disk device interface, the redundant data generator and the data transfer control unit of the user data transfer control unit by the disk array control unit, a host data bus for conducting the data transfer between the host interface and the memory by the data transfer control unit in the user data transfer control unit and a drive data bus for conducting the data transfer between the disk device interface and the memory by the data transfer control means in the user data transfer control unit are provided, and the data transfer control unit allows the designation of a plurality of data transfer paths between the areas of the memory and the disk device interface and the input of the data of the corresponding data transfer paths to the redundant data generator.

The present invention further provides a disk array controller or a disk array system characterized by the provision of a disk array control unit having one or more MPUs; and the provision of a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generator for generating redundant data, a multi-channel disk

device interface and data transfer control unit having one or more channels for controlling the data transfer between the host interface, the memory, the redundant data generator and the disk device interface; and that a control bus for controlling the disk device interface, the redundant data generator and the data transfer control unit of the user data transfer control unit by the disk array control unit, a host data bus for conducting the data transfer between the host interface and the memory by the data transfer control means in the user data transfer control unit and a drive data bus for conducting the data transfer between the disk device interface and the memory by the data transfer control unit in the user data transfer control unit are provided, and redundant data for the user data is generated in the redundant data generator and transferred to the disk device interface.

Namely, the present invention relates to a disk array controller characterized by the provision of a user data transfer control unit comprising a single or multi-channel host interface, a disk cache, a single or multi-channel DMAC, a redundant data generator and a multi-channel disk device interface and a disk array control unit having one or more MPUs. It further comprises a control bus (MPU bus) by the MPU, a host data bus for conducting the data transfer between the host interface and the disk cache and a drive data bus for conducting the data transfer between the disk device interface and the disk cache.

With this arrangement, in the disk array controller, even if inexpensive SCSI interface is used for the host interface and the disk device interface, the usage factor of the internal bus is reduced by the arrangement of the control bus (MPU bus), the host data bus and the drive data bus and the transfer rate of the internal bus is improved so that a disk array system which is inexpensive and has a higher data transfer rate is attained.

Further, in the above arrangement, the data scattering/gathering is attained by the transfer using a plurality of paths between areas on the disk cache and the disk device interface.

By the above arrangement, the generation of redundant data (the generation of parity data) is attained by using the data stored in the disk cache by the transfer using the plurality of paths between the areas on the disk cache and the parity generator. The redundant data generator (parity data generator) is directly coupled to the data transfer control means (DMAC) and allows the input of the data on the corresponding data transfer paths to the parity generator between the areas on the disk cache and the disk device interface, and transfers the data on the disk cache to both the disk device interface and the parity generator to allow the direct transfer of the generated redundant data (parity data) to the disk device without transferring it to the disk cache. Thus, the traffic to the disk cache during the generation of the redundant data (the generation of the parity data) is significantly reduced and an effective transfer rate in the disk array

system for a write command to a large capacity and continuous areas is improved.

BRIEF DESCRIPTION OF DRAWINGS

Fig. 1 shows a configuration of one embodiment of a disk array system having a host computer in accordance with the present invention,

Fig. 2 shows a performance of a disk device used in the disk array system of the present invention,

Fig. 3 illustrates the use of a DMAC of the present invention in the data transfer between a disk cache and a disk device,

Fig. 4 illustrates the use of the DMAC of the present invention in the data transfer between the disk cache, a parity generator and the disk cache,

Fig. 5 illustrates the use of the DMAC of the present invention in the transfer between the disk cache and the disk device and in the abreast transfer between the disk cache, the parity generator and the disk cache.

BEST MODE FOR CARRYING OUT THE INVENTION

Referring to Figs. 1~5, an embodiment of the present invention is explained specifically. Fig. 1 shows a configuration of a system comprising a host computer 17 and a disk array system 18 in accordance with one embodiment of the present invention. The host computer 17 and the disk array system 18 are connected through a host interface 3. The host interface 3 is of one channel and SCSI-2 having a two-byte width and a maximum transfer rate of 20 MB/s. The host interface 3 may be of multi-channel. The host computer 17 accesses the disk array system 18 in accordance with the SCSI (Small Computer System Interface, a kind of small computer peripheral device interface, standardized by ANSI) protocol through the host interface 3.

The disk array system 18 comprises an array controller 1 and a plurality of disk devices 2. The disk array device 18 adopts an architecture such as RAID5 and a RAID5 redundancy is one parity disk for four data disks, and five disk devices are a unit for forming a column of the RAID5. The disk array controller 1 has a five-channel drive interface 16 and connects a plurality of disk devices 2. The drive interface 16 is of SCSI-2 having one-byte bus width and a maximum transfer rate of 10 MB/s.

Fig. 2 shows a performance of the disk device 2 used in the disk array system 18. Namely, a spindle rotation speed in the disk device is 5400 rpm, a means seek time is 9 ms, a sustain data transfer rate is 7.2 MB/s and a SCSI data transfer rate is 10 MB/s.

A configuration of the disk array controller 1 is now explained. The array controller 1 comprises a disk array controller having an MPU 8, an MPU controller 9, a ROM 9 and a working RAM 11, a user data transfer control unit having a host interface controller 4, a disk cache 5 formed by a DRAM for temporarily storing data at a

high speed, a DMAC (Direct Memory Access Controller, a portion of a small computer which controls, in place of a CPU and an I/O processor, the data transfer between memory↔memory or between memory↔I/O. It generates a source address and a destination address necessary for the data transfer and drives a read cycle of the source and a write cycle of the destination) 6 and a parity generator (redundant data generator) 7 and drive interface controllers 12a~12e provided one for each of the five channels of drive interfaces, and three buses including a host data bus 13, a drive data bus 14 and an MPU bus 15. The MPU 8 writes and reads for the working RAM 11 in accordance with a program stored in the ROM 10 to control the DMAC 6, the parity generator 7 and the drive interface controllers 12a~12e of the user data control unit through the MPU bus 15. The DMAC 6 controls the user data transfer over the host data bus 13 and the drive data bus 14 and conducts the data scattering/gathering which is inherent to the RAID5. The parity generator 7 generates parity data which is the redundant data to the user data and conducts the regeneration of the user data when one of the disk devices 2 failures. The parity generator 7 is directly coupled to the DMAC 6 and is located between the disk cache 5 and the drive data bus 14.

The host data bus 13 is a user data transfer bus between the host interface controller 4 and the disk cache 5. The drive data bus 14 is a user data transfer bus between the disk cache 5 and the drive interface controllers 12a~12e. The MPU bus 15 is a control bus for controlling the DMAC 6, the parity generator 7 and the drive interface controller 12a~12e of the user data control unit.

By arranging the three buses 13, 14 and 15, the host interface controller 4 and the drive interface controller 12 may employ the SCSI control LSI which is inexpensive and has a maximum transfer rate of 20 MB/s. Namely, by arranging the three buses 13, 14 and 15, the data transfer between the host 17 and the disk cache 5 and the data transfer between the disk cache 5 and the disk devices 2a~2e can be concurrently conducted without requiring a dedicated circuit such as FIFO (First-in First-out) other than the SCSI control LSI between the host interface 3 and the host data bus 13 and between the drive interface 16 and the drive data bus 14. Since the maximum transfer rate of the SCSI-2 having the two-byte bus width in the host interface 3 which in the interface with the host 17 or the user is 20 MB/s as defined by the standard, the transfer rates of the host data bus 13 and the drive data bus 14 are 20 MB/s, respectively, and the data transfer rate of the disk cache 5 is 40 MB/s because the transfer between the host 17 and the disk cache 5 and the transfer between the disk cache 5 and the disk devices 2a~2e are concurrently conducted, and the data transfer may be sufficiently conducted.

The DMAC 6 has three channels, channel 1, channel b and channel c so that the abreast transfer using the three channels may be attained. Namely, the chan-

nel a is used for the transfer between the disk cache 5 and the disk devices 2a~2e, the transfer between disk cache 5-parity generator 7-disk cache 5 and the transfer between disk cache 5-parity generator 7-disk devices 2a~2e. The channel b and the channel c are used exclusively used for the data transfer between the disk cache 5 and the disk devices 2a~2e and between the host 17 and the disk cache 5.

The function of the channel a in the DMAC 6 and the data transfer by the channel a in the DMAC 6 are now explained. In the DMAC 6, five cache address counters 201 for the channel a, five port designation registers 202 corresponding to the five cache address counters 201 and five abreast transfer designation registers 205 corresponding to the cache address counters 201 are provided. The cache address counter 201 is a counter for designating an address of an area 203 on the disk cache 5. The port designation register 202 is a register for designating a channel of the drive interfaces 16a~16e corresponding to the cache address counters 202 or the parity generator 7. By the cache address counters 201 and the corresponding port designation registers 202, the five-channel path 204 may be designated between the disk cache 5 and the drive interfaces 16a~16e or between the disk cache 5 and the parity generator 7. The channel a in the DMAC 6 has a function to sequentially transfer data of predetermined unit of a plurality of designated transfer paths 204 in a time-division fashion. The abreast designation register 205 is a register for designating the abreast transfer of the data of the corresponding paths 204 to the parity generator 7. The channel a in the DMAC 6 has a function, in addition to the transfer function by the plurality of paths 204, to conduct the abreast transfer of the data of the plurality of paths 204 to the parity generator 7.

Fig. 3 illustrates the use of the channel a in the DMAC 6 in the data transfer between the disk cache 5 and the disk devices 2a~2e.

Fig. 4 illustrates the use of the channel a in the DMAC 6 in the data transfer between disk cache 5-parity generator 7-disk cache 5.

Fig. 5 illustrates the use of the channel a in the DMAC 6 in the abreast transfer between disk cache 5-parity generator 7-disk device 2e.

As shown in Fig. 3, the MPU 8 designates the addresses of the areas 203a~203e of the disk cache 5 to the cache address registers 201a~201e in the channel a of the DMAC 6 through the MPU bus 15 and designates the channels of the drive interfaces 16a~16e to the port designation registers 202a~202e corresponding to the cache address registers 201a~201e so that it may designate five paths between the areas 203a~203e on the disk cache 5 and the drive interfaces 16a~16e. The disk device 2 for the data transfer is preselected by issuing a SCSI command and the paths of the drive interfaces 16a~16e-disk devices 2a~2e are present one for each channel of the drive interfaces 16a~16e.

Accordingly, when the transfer function by the plu-

ality of paths 204a~204e of the channel a is used in the DMAC 6, the user data stored in the disk cache 5 from the host through the host data bus 13 may be divided into predetermined sizes called stripe sizes and scatter-transferred to a plurality of disk devices 2a~2e. Even when the user data is stored in a plurality of discontinuous areas on the disk cache 5, the data in any five areas 203 on the disk cache 5 may be scatter-transferred to different disk devices 2a~2e.

By changing the data transfer direction from the disk device 2 to the host 17, the data from the plurality of disk devices 2a~2e may be gather-transferred to continuous areas on the disk cache 5 by the transfer function by the plurality of paths.

Further, as shown in Fig. 4, by designating the parity generator 7 to the port designation registers 202a~202d and designating a plurality of paths 204a~204d between the plurality of areas 203a~203d and the parity generator 7 in the channel a of the DMAC 6, the parity data generation in the parity generator 7 by using the user data in the plurality of areas 203a~203d on the disk cache 5 by the transfer function based on the plurality of designated paths 204a~204d, and the transfer of the generated parity data to the area 203e of the disk cache 5 through the port designation register 202e and the cache address register 201e are attained.

Further, as shown in Fig. 5, the channel a in the DMAC 6 has a function, in addition to the data transfer by the plurality of paths 204a~204d, to abreast-input the transfer data of the paths 204a~204d to the parity generator 7 by the abreast transfer designation registers 205a~205d corresponding to the paths 204a~204d. Further, by using the remaining path 204e of the five channels, the output of the parity generator 7 may be stored in the disk device 2e through the cache address register 201e, the port designation register 202e and the abreast transfer designation register 205e so that the data transfer between the disk cache 5 and the disk devices 2a~2d and the abreast data transfer between disk cache 5-parity generator 7-disk device 2e in the channel a of the DMAC 6 are attained.

In the disk array system 18, the channel a and the channel b in the DMAC 6 are used for a read command for large capacity and continuous areas from the host 17 to concurrently conduct the data transfer between the disk devices 2a~2e and the disk cache 5 and the data transfer between the host 17 and the disk cache 5. For the data transfer between the disk devices 2a~2e and the disk cache 5, the transfer function by the plurality of paths 204a~204e of the channel a in the DMAC 6 is used to gather-transfer the data from the plurality of disk devices 2a~2e to the continuous areas on the disk cache 5.

In the disk array system 18, for a write command for large capacity and continuous areas from the host 17, the channel a and the channel b in the DMAC 6 are used to concurrently conduct the data transfer between the disk cache 5 and the disk devices 2a~2e and the data transfer between the host 17 and the disk cache 5.

For the data transfer between the disk cache 5 and the disk devices 2a~2d, the data transfer function by the plurality of paths 204a~204d of the channel a in the DMAC 6 and the function to abstract-input the transfer data on the paths 204a~204d to the parity generator 7 are used to concurrently transfer the data of the disk cache 5 to the plurality of disk devices 2a~2d and the parity generator 7 and transfer the parity data generated by the parity generator 7 to the cache address register 201e, the port designation register 202e and the abreast transfer designation register 205e, not through the disk cache 5 but directly through the path 204e.

In the present embodiment, the disk array controller comprises a single processor and the host interface controller 4 and the drive interface controller 12 employ commercially available SCSI control LSI which is inexpensive and has a maximum transfer rate of 20 MB/s and no dedicated circuit such as FIFO other than the SCSI control LSI is present between the host interface 3 and the host data bus 13 and between the drive interface 16 and the drive data bus 14 so that the cost of the disk array controller is reduced by a factor of five compared to a disk array controller comprising a multi-processor (eight MPUs) and the MPU bus 15 and two internal buses 13 and 14 as the user data transfer buses, and the cost of the disk array system 18 can be reduced.

In the disk array system 18, the parity data generated by the parity generator is directly transferred to the disk device so that the effective transfer rate of the write command for the large capacity and continuous areas from the host 17 can be improved by approximately 40% compared to a system which temporarily store the parity in the disk cache 5.

Further, since the SCSI-2 which will extend as a standard interface is used as the drive interface 16, a high performance disk array system may be constructed by the connection with a future high performance disk device.

In accordance with the present invention, the user data control unit and the disk array controller are provided and at least three buses, the control bus (MPU bus), the host data bus and the drive data bus are arranged. Thus, the use of the inexpensive interface controller LSI as the host interface controller and the drive interface controller is allowed and the cost of the disk array controller as well as the disk array system can be significantly reduced.

Further, in accordance with the present invention, the transfer rate of the internal bus of the disk array controller is not the performance neck of the disk array system and the transfer rate of the internal bus can be increased and the bus width can be reduced.

Further, in accordance with the present invention, the traffic of the disk cache during the parity generation is reduced in the disk array controller and the effective transfer rate of the disk array system for the write command for the large capacity and continuous areas from the user can be increased.

Claims

1. A disk array controller characterized by:

the provision of a disk array control unit having one or more MPUs; and
the provision of a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface; and
that a control bus for controlling said disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided.

2. A disk array controller according to Claim 1 characterized by that said host interface comprises a SCSI interface.

3. A disk array controller according to Claim 1 characterized by that said disk device interface comprises a SCSI interface.

4. A disk array controller according to Claim 1 characterized by that said data transfer control means allows the designation of a plurality of data transfer paths between areas of said memory and said disk device interface.

5. A disk array controller according to Claim 1 characterized by that said data transfer means comprises a plurality of counters for designating addresses of said memory and a plurality of registers for designating channels of said disk device interface corresponding to the respective counters.

6. A disk array controller according to Claim 1 characterized by that data is transferred between the areas of said memory and said redundant data generation means by using a plurality of transfer paths.

7. A disk array controller according to Claim 1 characterized by that said data transfer control means

comprises a DMAC.

8. A disk array controller according to Claim 1 characterized by that said data transfer control means comprises a plurality of counters for designating addresses of said memory and a plurality of registers for designating channels of said disk device interface corresponding to said counters to allow the designation of a plurality of data transfer paths between the areas of said memory and said disk device interface and the input of the data of the corresponding data transfer paths to said redundant data generation means.
9. A disk array controller according to Claim 1 characterized by that said disk device interface is provided with drive interface controller one for each channel.
10. A disk array controller characterized by:
 - the provision of a disk array control unit having one or more MPUs; and
 - the provision of a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface; and
 - that a control bus for controlling said multi-channel disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided, and said redundant data generation means is directly coupled to said data transfer control means and arranged between said memory and said drive data bus to reduce the traffic to said memory during the generation of the redundant data.
11. A disk array controller characterized by:
 - the provision of a disk array control unit having one or more MPUs; and
 - the provision of a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant

data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface; and

that a control bus for controlling said disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided, and said data transfer control means allows the designation of a plurality of data transfer paths between the areas of said memory and said disk device interface and the input of the data of the corresponding data transfer paths to said redundant data generation means.

12. A disk array controller characterized by:

- the provision of a disk array control unit having one or more MPUs; and
- the provision of a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface; and
- that a control bus for controlling said disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided, and redundant data for the user data is generated in said redundant data generation means and transferred to said disk device interface.

13. A disk array system characterized by:

a disk array controller comprising a disk array control unit having one or more MPUs and a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface, wherein a control bus for controlling said disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided; and
a plurality of disk devices connected to said disk device interface of said disk array controller.

14. A disk array system characterized by:

a disk array controller comprising a disk array control unit having one or more MPUs and a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface, wherein a control bus for controlling said multi-channel disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided, and said redundant data generation means is directly coupled to said data transfer control means and arranged between said memory and said drive data bus to reduce the traffic to said memory during the generation of the redundant

data; and

a plurality of disk devices connected to said disk device interface of said disk array controller.

15. A disk array system characterized by:

a disk array controller comprising a disk array control unit having one or more MPUs and a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface, wherein a control bus for controlling said disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided, and said data transfer control means allows the designation of a plurality of data transfer paths between the areas of said memory and said disk device interface and the input of the data of the corresponding data transfer paths to said redundant data generation means; and
a plurality of disk devices connected to said disk device interface of said disk array controller.

16. A disk array system characterized by:

a disk array controller comprising a disk array control unit having one or more MPUs and a user data transfer unit having a host interface with a host computer, a memory for temporarily storing data, redundant data generation means for generating redundant data, a multi-channel disk device interface and data transfer control means having one or more channels for controlling the data transfer between said host interface, said memory, said redundant data generation means and said disk device interface, wherein a control bus for controlling said disk device interface, said redundant data generation means and said data transfer control means of said user data transfer control unit by said disk array control unit, a host data bus for

conducting the data transfer between said host interface and said memory by said data transfer control means in said user data transfer control unit and a drive data bus for conducting the data transfer between said disk device interface and said memory by said data transfer control means in said user data transfer control unit are provided, and redundant data for the user data is generated in said redundant data generation means and transferred to said disk device interface; and
a plurality of disk devices connected to said disk device interface of said disk array controller.

17. A disk array system according to Claim 13, 14, 15 or 16 characterized by that said data transfer control means in said disk array controller comprises a DMAC.

18. A disk array system according to Claim 13, 14, 15 or 16 characterized by that said host interface comprises a SCSI interface.

FIG. 1

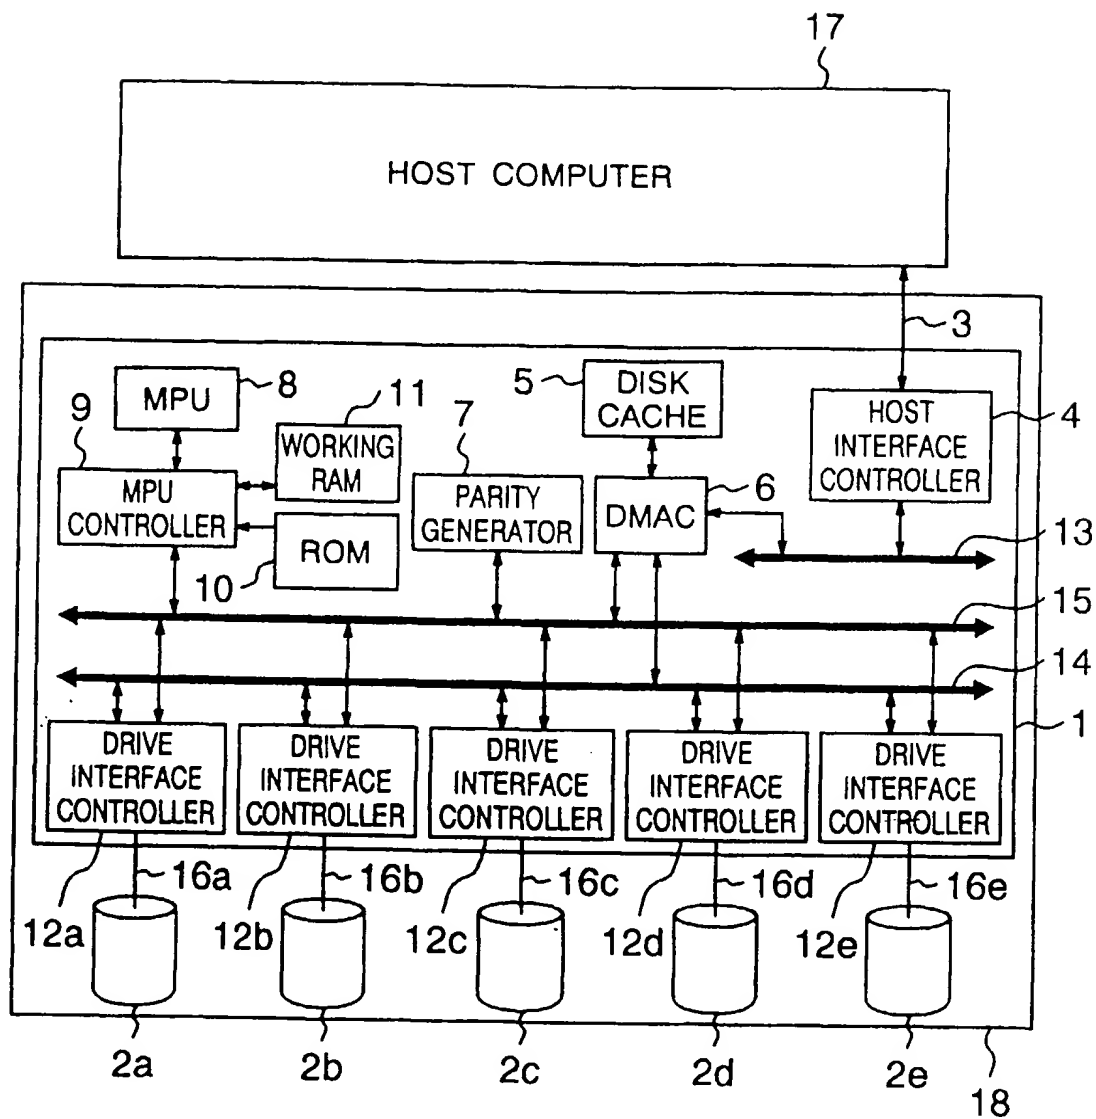

FIG. 2

ITEM	PERFORMANCE
SPINDLE ROTATION SPEED (rpm)	5400
MEAN SEEK TIME (ms)	9
SUSTAIN DATA TRANSFER RATE (MB/s)	7.2
SCSI DATA TRANSFER RATE (MB/s)	10

FIG. 3

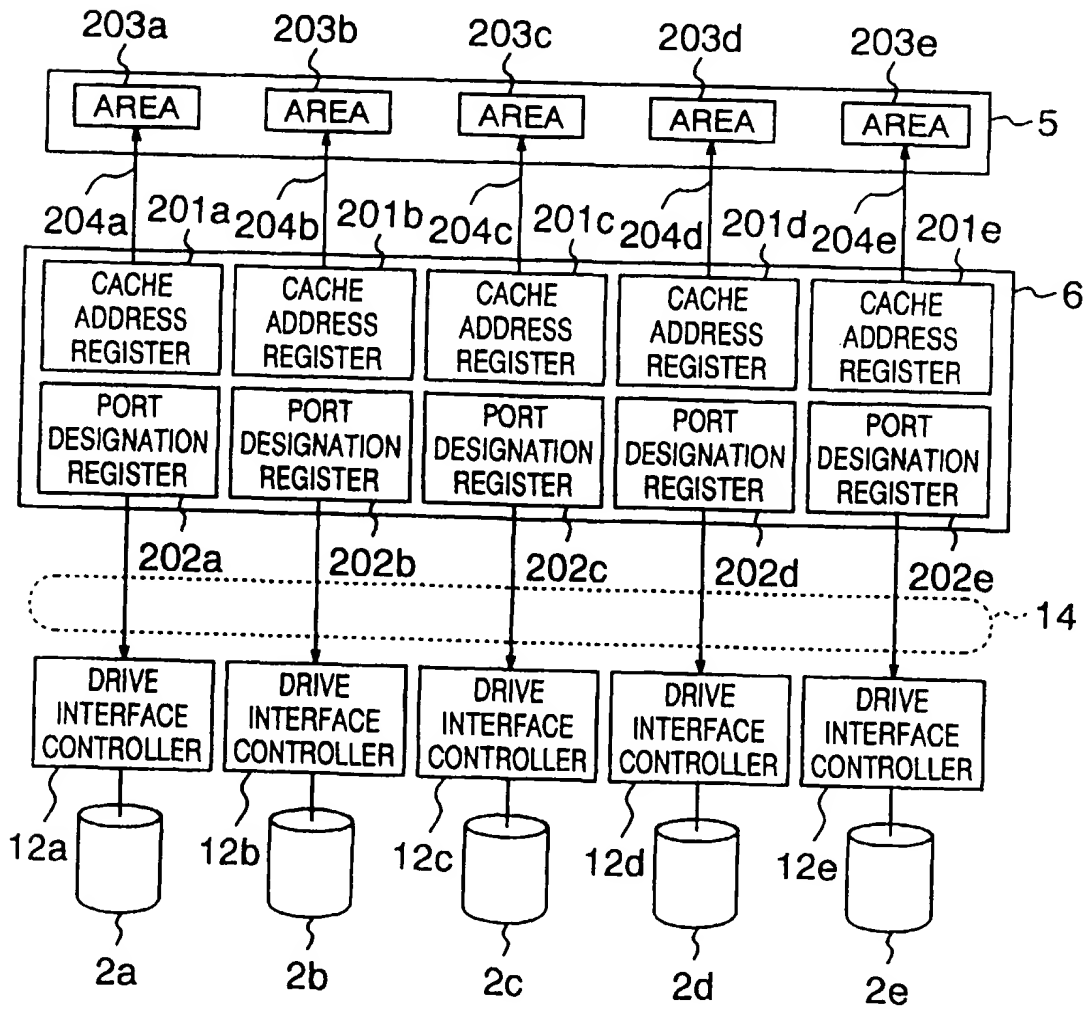

FIG. 4

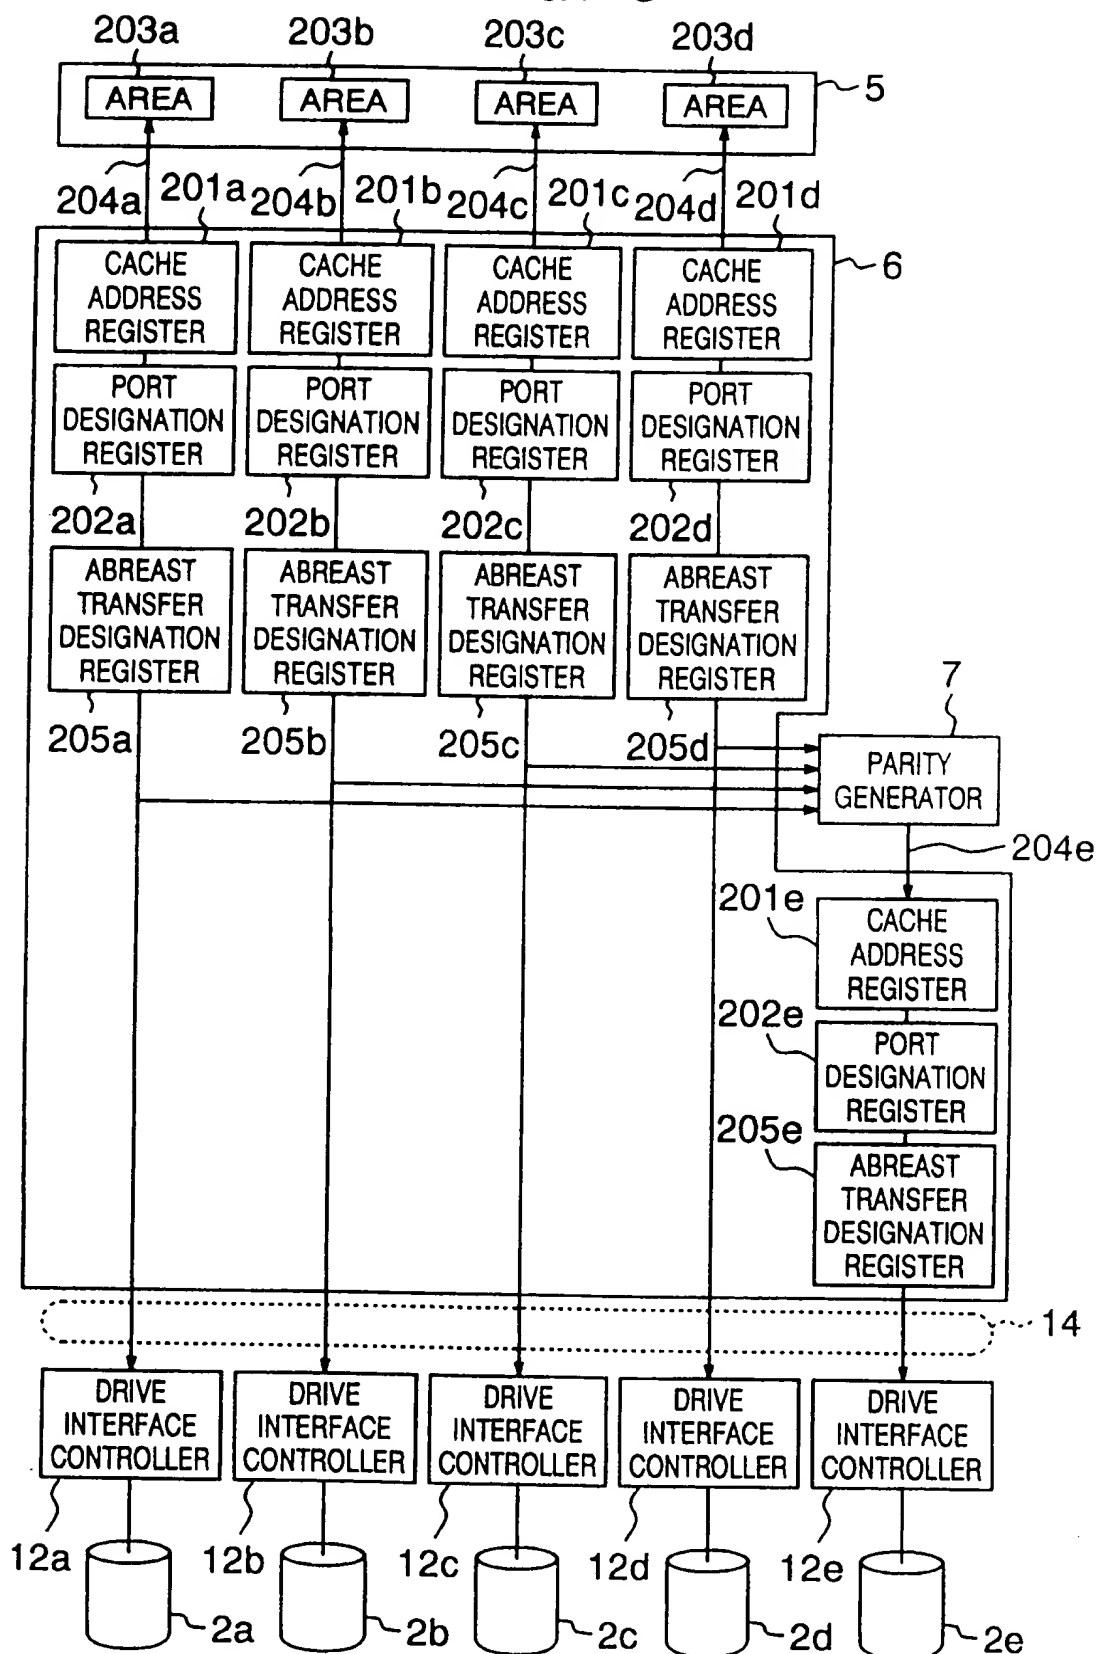

FIG. 5

INTERNATIONAL SEARCH REPORT

International application No.

PCT/JP95/02299

A. CLASSIFICATION OF SUBJECT MATTER

Int. C1⁶ G06F3/06

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

Int. C1⁶ G06F3/06

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Jitsuyo Shinan Koho 1926 - 1995

Kokai Jitsuyo Shinan Koho 1971 - 1995

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

☐ Further documents are listed in the continuation of Box C.☐ See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family
